Acknowledgements

We gratefully acknowledge the financial support provided by the US Environmental Protection Agency and the efforts of the United Nations Environmental Programme in Nairobi, for this study. We particularly want to thank Ms. Jane Metcalf, U.S. EPA Office of International Affairs, and Mr. John Koupal, U.S. EPA Office of Mobile Sources, as well as Rob De Jong, UN Environmental Office.

Chapter One: **Overview**

A necessary information base for the calculation of on-road vehicular emissions is the distribution of technologies that are operating on the roads and at the times of interest. This distribution must relate to the amount of driving that is being carried out by each type of technology. A simple approach is to randomly count the number and types of vehicles that are operating on the roads and at the times of interest. Such a count will relate to the rate of driving of the various vehicular technologies recorded since they will be observed in the proportion to the amount of driving that is occurring.

A problem with this approach is the difficulty in making such counts on busy multilane roads and identifying the attendant technologies in real time. This problem can be partially remedied by video taping the traffic. The videotapes can then be studied at leisure and in slow motion to achieve accurate vehicle counts and to identify, to a degree, attendant technologies. Modern digital tapes can be freeze-framed as needed producing relatively high-resolution pictures for careful study if necessary. This approach was used in Los Angeles [Malcolm et. al., 2002] to acquire license plate numbers with excellent results.

Even with the resulting resolution, however, it is very difficult or impossible with respect to most vehicles to determine actual engine technologies, fuel, and emissions controls. The odometer readings of the vehicles are also not accessible using this approach. Even with this limitation, it is easy to review videotapes to establish the relative numbers of passenger cars compared to trucks, buses, and taxis and to make a reasonable estimate of vehicle sizes and even ages by simply carefully observing the collected tapes.

The variety of technologies with respect to passenger cars can vary widely in the modern fleet. In a developing country, the passenger vehicle fleet can contain uncontrolled, carbureted vehicles operating alongside modern multi-point injection, 3-way catalyst vehicles with emissions that are 1% of the uncontrolled vehicles. It is important to understand the relative proportions of passenger vehicle technologies to properly evaluate the emissions of the on-road fleet. Vehicle registration information is often used to establish these types of information in the United States and elsewhere. Unfortunately, such information is often not available or unreliable in developing countries. An alternate process is to examine an appropriate subset of the passenger vehicle fleet in the region of interest to establish information on the distribution of specific passenger vehicle technologies. Since stopping vehicles for this purpose is not normally practical, an alternate approach is to examine vehicles that are parked at representative locations in the region of interest. The assumption that must be made is that the observed vehicular technologies found in grocery store, shopping center, and industrial parking lots and roadside parking are reasonably representative of vehicular activity. A comparative study

of parked vehicles with on-road vehicle activity near the parking lots has confirmed that similar results are achieved. [Malcolm et. al., 2002].

The range of vehicular technologies associated with trucks and buses are typically more limited today especially in developing countries. Thus, the videotape information is adequate for most analysis. If the variety of vehicular technologies associated with buses and trucks should be significantly subdivided, then trucks and buses can be randomly inspected to establish the distribution of technologies. Care must be taken in this process to examine these technologies in a manner that produces results in reasonable proportion to vehicular activity.

This study consists of the collection of data by video taping vehicles on roads and by randomly sampling parked vehicles. The parked car sampling process was carried out over several days and collected data on close to a thousand vehicles. The video taping process allowed the collection of information on several thousand vehicles. A similar study was carried out in Santiago, Chile in Fall 2001.

Chapter Two: Videotaping Vehicular Activity

Digital video cameras were used for the capture of on-road traffic. A two-person team, a person from CE-CERT and a local associate, was used to setup and operate the videotaping cameras. Two cameras were used to capture information at each location. One camera was set up to observe all lanes of traffic and a second camera was set up to observe vehicle detail and vehicle occupancy. The tapes that looked at all lanes were reviewed to make appropriate vehicular counts for traffic analysis. The close-up tapes will be reserved for later analysis of vehicle occupancy.

Videotaping was carried out over six days within a period of 6 hours each day. The three locations videotaped consisted of a generally low-income area, a commercial area, and an upper income area. In each of these areas, three types of roads were videotaped consisting of a major arterial (or freeway if available), a local arterial, and a residential street. This results in videotapes collected from nine representative locations in the region of interest. In order to create as much randomness in the observations as possible, videotaping was carried out for 20-minute intervals in each hour and then the cameras were rotated to the next roadway type.

The videotaping was alternated on different days between the morning and the evening. The morning hours used were 7am to 1pm. one day and the evening hours used were 3pm until 9pm.¹ Three 20 minute tapings were collected on each one-hour digital videotape resulting in 24 videotapes for the two cameras at the nine locations over six days.

The videotapes were reviewed in the office and the observed traffic broken into 12 categories indicated by an “X” in Table 2.1. Figure 2.1 shows the videotaping process.

Table 2.1: Vehicle Technologies Recorded from Digital Videotapes

Vehicle Size	Passenger Cars	Trucks	Buses	Taxis	Motorcycles
Small	X	n/a	X	X	X
Medium	X	X	X	X	n/a
Large	X	X	X	X	n/a

¹ The intention is to record a morning and evening in each location of interest. In the case of Santiago, Chile, the desired time order was disrupted so that the videotaping in the upper income area occurred in the morning hours while the videotaping in the lower income area occurred in the evening hours. This provided duplicate data to look at variability. However, in Nairobi, the observation times were set up to provide data over a wider range of hours.

Tables 2.2a-c show the results from the videotaping for the nine sites that were monitored.

Overall, the passenger vehicles observed to be operating in Muthaiga, the higher income district, were larger sized vehicles (~35%) than the fraction of larger sized passenger vehicles operating in BuruBuru (~17%), a generally lower income district. This data is consistent with the Santiago findings. Wealthier people in these areas tend to buy larger vehicles. The vehicles in the US fleet have been getting larger in recent years in the U.S. during the strong economy. As the economies improve in developing countries, it is likely that the sizes of vehicles operating in the fleet will tend to grow as well. UN officials in Nairobi note that vehicle sizes have grown dramatically especially over the past decade. The relative distributions of passenger vehicles, buses, motorcycles, and trucks are shown in Figure 2.2. It should be noted that it is very likely that the taxis are undercounted in the previous tables. In Nairobi, the taxis are not required to be marked and more than half of the taxis (according to estimates by local taxi drivers) are unmarked. These vehicles serve as both personal and taxi vehicles and the drivers prefer that they are not marked.

Table 2.3 presents a comparison of data collected in Los Angeles, Nairobi, and Santiago. In all three locations, passenger cars clearly dominate the fleet. Passenger car fractions are greatest in the U.S. data at more than 95% of the fleet. There are clearly fewer motorcycles and buses in the U.S. compared to Nairobi or Santiago.

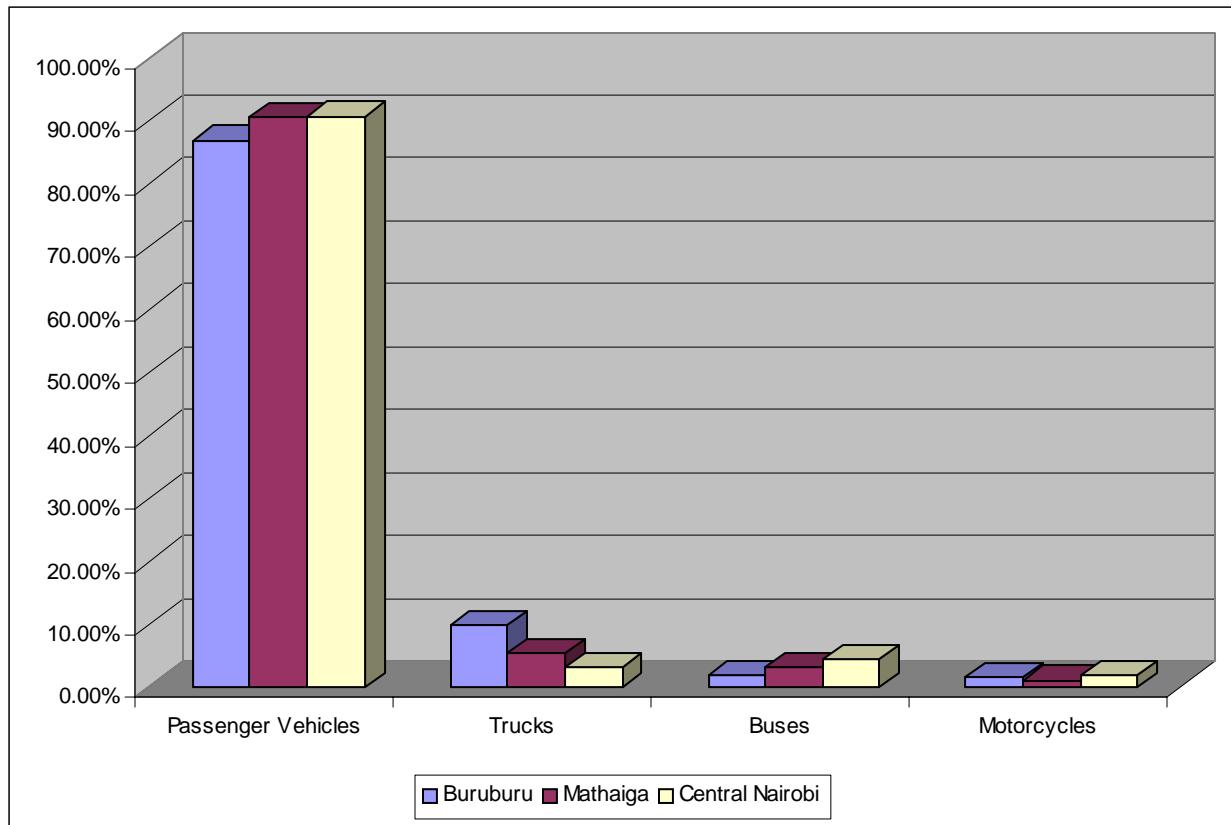

Figure 2.2: Distribution of Passenger Vehicles, Buses, Motorcycles, and Trucks in Parts of the Nairobi Metropolitan Area Based on Video Collected Data

Table 2.3: Comparison of General Vehicle Populations in Los Angeles, Nairobi and Santiago

	Passenger Veh.	Trucks	Buses	Motorcycles

Chapter Three: Parked Vehicle Technology Recording

A two-person team visited grocery store, shopping center, and business parking lots, and roadside parking in each of the areas selected for videotaping. Parked car data collection was carried out over the same 6-hour period that videotaping occurred.

One team member recorded general information about the vehicle while the second team member collected odometer readings where visible, transmission type, and air conditioning information by looking through the vehicle windows. A third team member photographed each vehicle to provide a permanent record of data collected. Figure 3.1 illustrates the data collection process and Table 3.1 indicates the vehicle parameters collected.

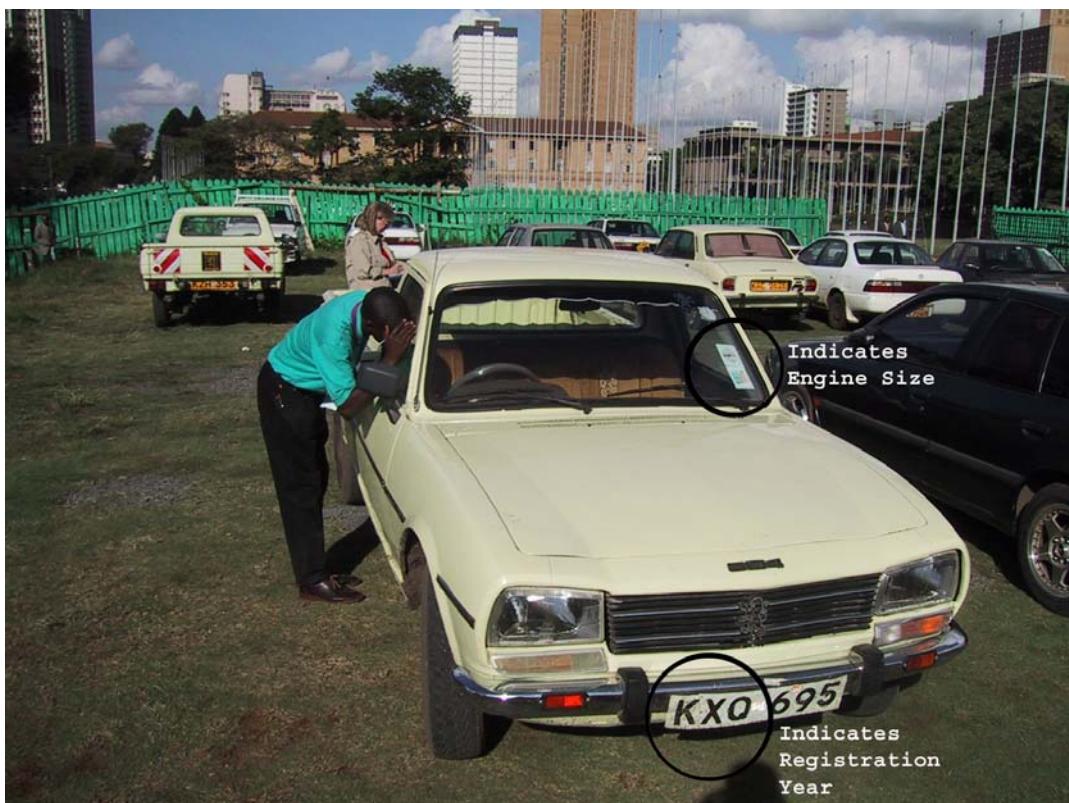

Figure 3.1: Parked Car Data Collection in Central Nairobi

Table 3.1: Vehicle Information Recorded

Information Collected	Comment
Manufacturer	Almost always available
Model	Almost always available
Engine Size (liters)	Almost always indicated on the vehicle.
Registration Year/Model Year	Registration year was always estimated from license plate. Model year was estimated by observation.
Vehicle Condition	Subjective estimation.
Catalyst	Nairobi has a large used car market with vehicles primarily from Japan. Random observations indicated that virtually all of these vehicles had catalyst. However, all gasoline sold in Nairobi up until a month before the study began was leaded. Thus, all vehicles were recorded as non-catalyst.
Odometer Reading	Recorded by looking through the window. Not visible in some cases and many 2001/2002 vehicles have digital odometers, which are not visible when the vehicle is not operating.
Transmission Type	Recorded by looking through the window of the vehicle
Air Conditioning	Recorded by looking through the window of the vehicle.
Fuel Type	Based on indication on vehicle. Otherwise by knowledge of the vehicle model and looking at the exhaust pipe.
Licenses Number	Recorded from vehicle plates.

The data collected in the walk-around portion of the study is presented in Appendix A. Data from 865 vehicles were collected over six days of field studies. While this represents a significant dataset, there is still the potential for sampling errors especially in cases where the data is parsed into subgroups. A fundamental assumption used in this study is that people act somewhat randomly around norms producing driving statistics that should represent relatively smooth patterns with a standard statistical type of character. When samples appear to differ from these smooth patterns, it is assumed that traditional processes such as least square fits and other curve smoothing processes will work to improve the representativeness of the acquired data.

Passenger Vehicles

Fleet Distribution

Passenger vehicles makeup almost 89% of the on-road fleet and are thus a key concern for vehicle analysis. Because only leaded fuel has been available in Nairobi in the past,

all Nairobi vehicles were treated as having no catalyst.³ Most vehicles in Nairobi actually had catalyst since they were used cars bought from developed countries. Table 3.2 provides some comparative data for the Nairobi fleet. As can be seen, the vehicles in the poorer section of the city tend to be older, smaller engine, and of higher mileage compared to the wealthier part of Nairobi.

Table 3.2: Comparison of Key Passenger Fleet Data Summaries Over Nairobi Metro Area

Location	Average Model Year	Average Age at Registration	Average Usage (Km)	Average Engine Size (l)	Air Conditioning	Automatic Transmission
Buruburu	1987.6	1994.0	162,153	1.60	47%	4.0%
Central Nairobi	1988.5	1995.3	128,414	1.59	62%	3.3%
Muthaiga	1992.4	1995.9	93,244	1.91	73%	6.7%
Taxi	1988.7	1994.2	122,480	1.50	73%	0%

The typical vehicle was about 6.2 years old when brought into Kenya. Air conditioning and automatic transmission fractions were consistent with income levels; although, a much higher fraction of vehicles in Nairobi had air conditioning than in Santiago. This is likely due to the fact that most Kenyan vehicles were brought in used from developed countries like Japan where air conditioning is common.

Figure 3.2 presents a comparison of model year data compared to Santiago and the United States [U.S. EPA]. The years are grouped to make the results more statistically robust.

³ One oil company in Kenya has offered unleaded fuel for sale since early 2002 on a voluntary basis. Thus, it will be possible for owners of catalyst vehicles to obtain leaded fuel, but all existing catalyst will have been destroyed by the lead in the fuel at the present time.

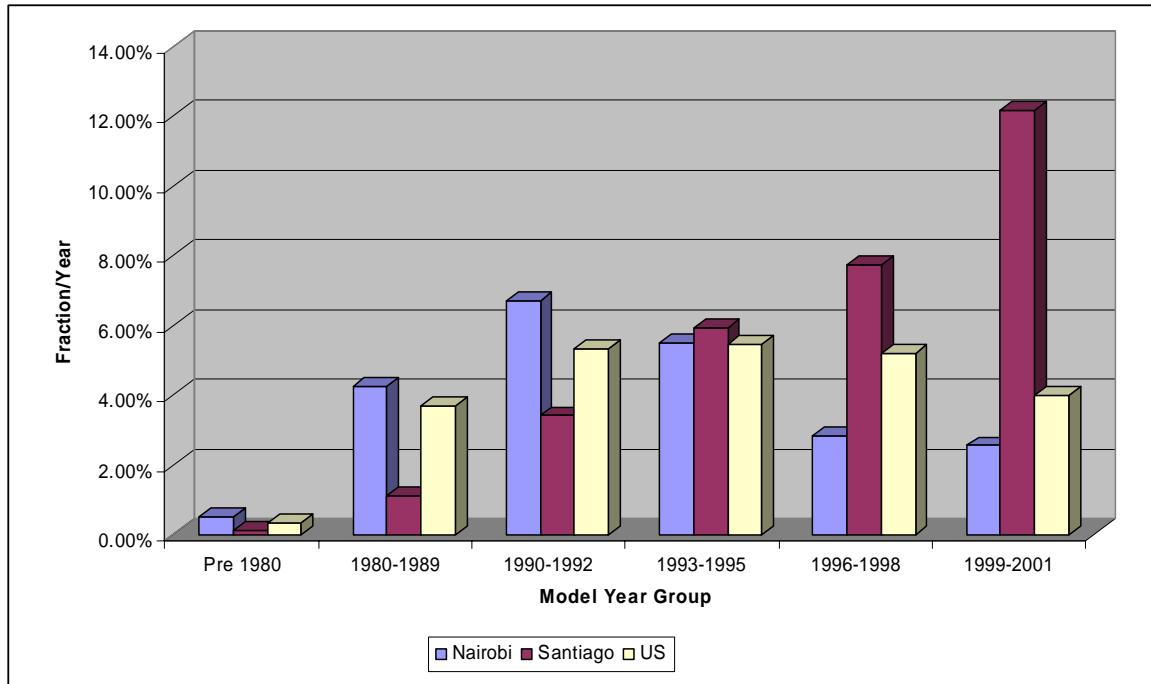

Figure 3.2: Comparison of Fraction of Various Model Years in the Nairobi Fleet Compared to the Santiago and US Fleets (fraction per year for each model year grouping)

As shown in Figure 3.2, the Nairobi fleet is the oldest fleet compared to the U.S. or Santiago. The relative distribution of the Nairobi fleet more closely resembles the U.S. fleet than does the Santiago fleet, which is actually newer than the U.S. fleet.

Figure 3.3 presents an analysis of the data collected in the Nairobi metropolitan area by individual model year. 1-year-old vehicles represent 2001 model year in this figure. Due to the overall sample size, there were as many as 132 vehicles in some age groups while only none in other age groups. Thus, model years were grouped for this analysis. In addition, 2001 and older vehicles will continue to be sold in Nairobi creating a continuing evolution of model year distributions in the future.

Figure 3.3: Model Year Distribution of the Metropolitan Nairobi Fleet

An important characteristic of the vehicle fleet is the size distribution of the passenger fleet. This will influence the fuel use by this sector of the fleet. Table 3.3 shows the overall passenger fleet vehicle distribution derived from the walk-around data broken into three size groups as used in the IVE model.

Table 3.3: Vehicle Engine Size Distribution in Various Parts of the Nairobi Metro Area

Location/Engine Size	Vehicle Count	Fraction
Buruburu		
Small (0.6-1.5 liter engine)	57	57.0%
Medium (1.6-2.4 liter engine)	39	39.0%
Large (2.4 and larger liter engine)	4	4.0%
Total	100	
Central Nairobi		
Small (0.6-1.5 liter engine)	349	68.4%
Medium (1.6-2.4 liter engine)	139	27.3%
Large (2.4 and larger liter engine)	22	4.3%
Total	510	
Muthaiga		
Small (0.6-1.5 liter engine)	91	40.4%
Medium (1.6-2.4 liter engine)	90	40.0%
Large (2.4 and larger liter engine)	44	19.6%
Total	225	
Overall		
Small (0.6-1.5 liter engine)	497	59.5%
Medium (1.6-2.4 liter engine)	268	32.1%
Large (2.4 and larger liter engine)	70	8.4%
Total	835	

As shown earlier in Table 3.2, the vehicle fleet tends to be larger in the Muthaiga section of Nairobi Metro compared to the Buruburu section of Nairobi Metro. Overall, 59.5% of the Nairobi Metro fleet is made up of small vehicles while 8.4% are large vehicles. Comparing this to Santiago data, 34.1% are smaller vehicles and 8.5%, almost the same as Nairobi, are larger vehicles. The numbers presented in Table 3.3 show the same trends as the video counts presented in Tables 2.2a,b,c but vary considerably from the actual fractions estimated from the videotapes. This difference illustrates the difficulty in estimating specific vehicle size from the videotapes and the need for the parking lot surveys. The more specific data from the parking lot surveys will be used where available.

Vehicle Activity

The determination of average vehicle usage in Nairobi was complicated by the fact that many of the vehicles operating in Nairobi were used when they arrived there. Thus, estimates cannot be made directly from the odometer readings observed in the parking lot surveys. Usage estimates were made by use of a multiple regression analysis based on the odometer reading and the years operated in Kenya (Present Date-Registration Date) compared to the years the vehicle operated before arriving in Kenya (Registration Data-Model Year Data). The regression produced the equation shown below:

$$\text{Accumulated Use (km)} = 4989 * (\text{Yrs Before Kenya}) + 19023 * (\text{Yrs in Kenya}) - 458.3 * (\text{Yrs in Kenya})^2$$

This result implies that the driving in Kenya averages about 16732 kilometers per year over the first five years of driving. The driving before arriving in Kenya was about 4989 kilometers per year. The result for driving before arrival in Kenya is absurdly low. This raises questions about the methodology or raises the possibility that the odometers are being run back before the vehicles are delivered in Nairobi. To test the annual driving in Nairobi, a subset of vehicles that were only driven in Nairobi was selected from the full data set. This resulted in an annual average usage of 17,837 kilometers per year at 5 years of age. This is in reasonable agreement with the multiple linear regression analysis on all of the vehicles implying that the multiple-regression seems to be reasonably accurate. This result also leads to the conclusion that vehicle odometers may be being run back before vehicles are delivered to Kenya. Figure 3.4 illustrates the least squares fit for vehicles operating their entire life in Kenya.

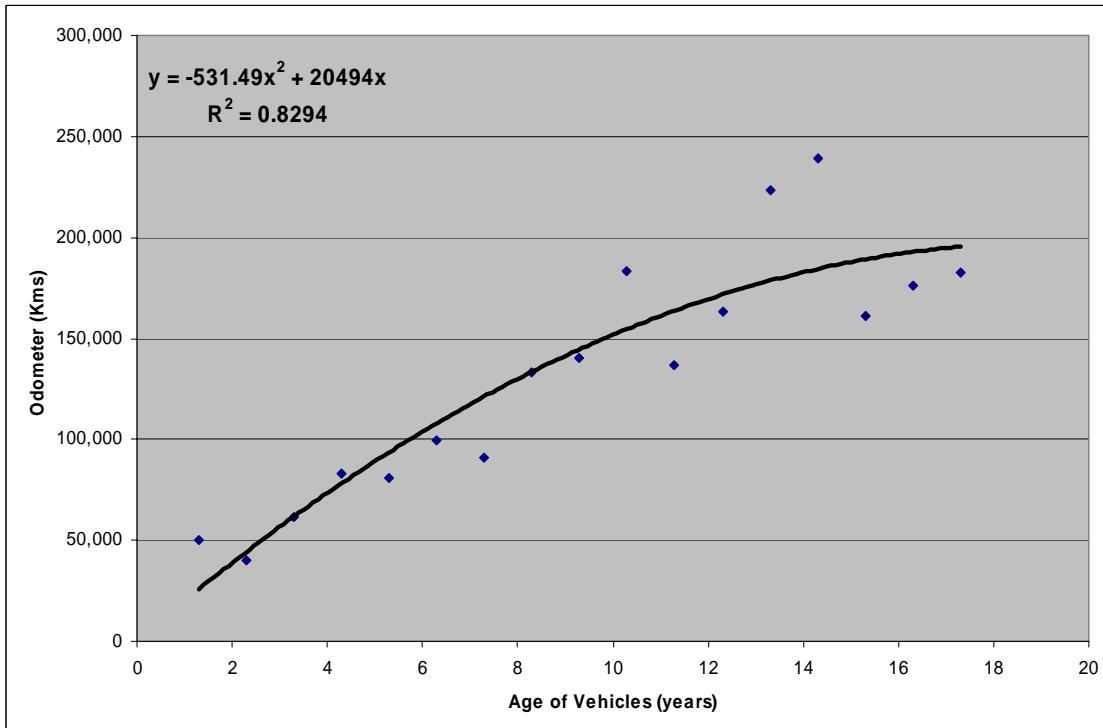

Figure 3.4: Mileage Accumulation for Vehicles Operated Solely in Nairobi

Figure 3.5 compares mileage accumulation for Santiago, Nairobi, and Los Angeles. As can be seen, the Nairobi driving is between that seen in Los Angeles and Santiago.

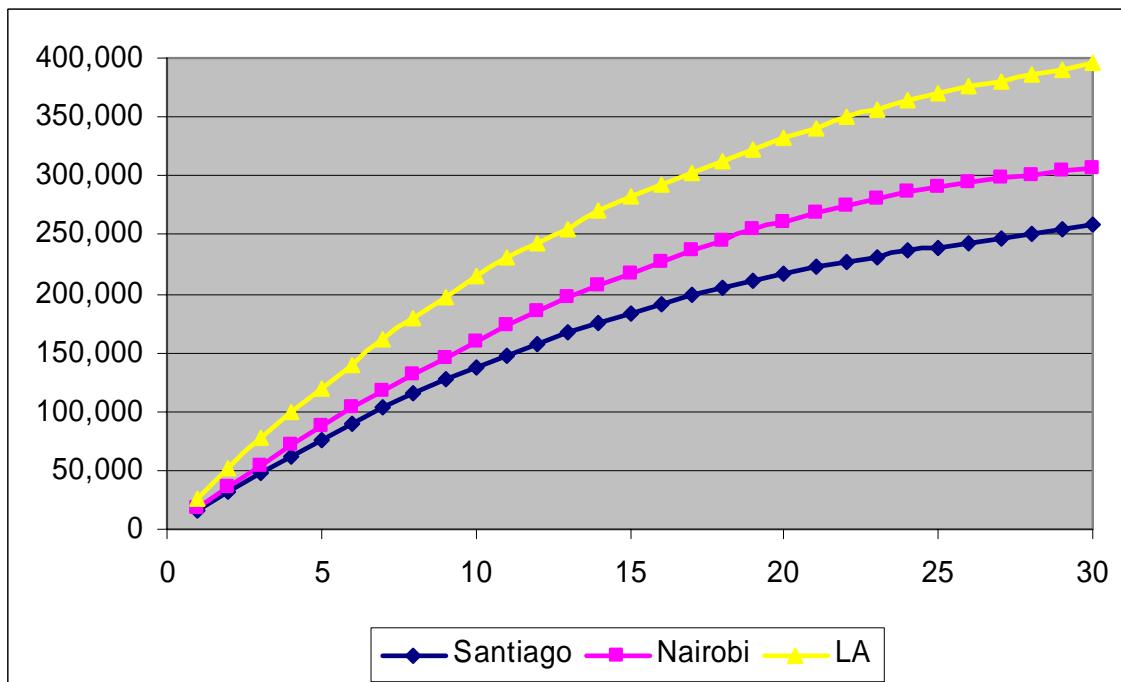

Figure 3.5: Comparison of Vehicle Usage by Age for Los Angeles, Nairobi, and Santiago

Since the odometer readings in Nairobi and Santiago were determined by collecting data in parking lots, it is possible, that the resulting average usage will be high compared to data, which looks at the entire fleet. This high bias results from the fact that it is more likely that the survey approach will find the more active vehicles since they are more likely to be found at supermarkets and shopping centers. These vehicles will have a higher average usage, which will lead to a high biased usage value. For example, Comision Nacional Del Medio Ambiente (CONAMA) reports that they believe that the typical usage is closer to 14,500 km per year [CONAMA] instead of the value of 16,600 km per year estimated from the Santiago parking lot surveys.

If it is assumed that the fleet observed in this portion of the experiment is representative of vehicle activity as opposed to base fleet composition, some corrections should be made to the data as follows.

Assume that

N_i = actual number of vehicles in the i th usage group in an urban area.

M_i = annual usage defined for the i th group.

Then,

$$\text{Total number of vehicles} = N_T = \sum N_i \quad (3.1)$$

$$\text{Total distance driven} = S_T = \sum (N_i * M_i) \quad (3.2)$$

$$\text{Average fleet usage} = A = S_T/N_T = (\sum (N_i * M_i)) / (\sum N_i) \quad (3.3)$$

If a total of K vehicles are randomly sampled then the probability of seeing a vehicle in the group is,

$$\text{Probability} = (N_i * M_i) / (\sum (N_i * M_i)) \quad (3.4)$$

and

$$\text{Likely number of vehicles observed} = No_i = K * (N_i * M_i) / (\sum (N_i * M_i)) \quad (3.5)$$

where

$$K = \sum No_i$$

Substituting equation (3.5) into equation (3.3) and solving for N_i yields,

$$N_i = (N_{oi}/K) * (S_T/M_i) \quad (3.6)$$

and

$$A = K / \left(\sum \left(N_{oi}/M_i \right) \right) \quad (3.7)$$

Equation (3.6) can also be rewritten as

$$(N_i/N_T) = (N_{oi}/K) / (M_i/A) \quad (3.8)$$

Equation (3.8) makes the point that the actual fraction of vehicles in the i th use group of the base fleet is equal to the fraction of vehicles observed in the i th use group divided by the ratio of mileage in the i th use group to the actual fleet average.

Table 3.4 indicates the observed usage distribution for vehicles in the 1994 to 2000 age group for Santiago. This group was selected for evaluation because the age of the vehicle is more reliable.

Table 3.4: Observed Vehicle Usage Distribution for Vehicles in the 1994-2000 Age Group

Annual Usage Range (1000s of Km)	Mid-Point of Annual Usage (Km)	Number of Vehicles Observed
0 to 9	5,000	81
10 to 19	15,000	387
20 to 29	25,000	131
30 to 39	35,000	27
40 to 49	45,000	9
50 to 59	55,000	6
60 to 69	65,000	2
Total Vehicles (K)		643

Using the values in Table 3.4 in equation (3.6) produces an actual average annual vehicle use of 13,300 Km for this group of 1994 to 2000 group of vehicles. These contrasts with the straight average of 16,600 Km noted earlier. If the surveyed data does correspond to the fleet activity distribution then the correct average driving for overall Santiago is 13,300 Km. As noted earlier, CONAMA reports that the average annual driving in Santiago is 14,500 Km. If the 14,500 reported by CONAMA is correct, then the straight average value of 16,600 Km per year is 14.5% higher than the reported value while the activity corrected factor is 8.2% below the reported value. This is not an issue for the fleet distributions developed in this report since the interest is in activity related distributions. However, it is an important consideration when comparing data collected from on-road counts or parking lot counts with data extracted from vehicle registration data in government data banks.

Table 3.5a uses the second order fit shown in Figure 3.4 to estimate accumulated vehicle driving and then to calculate annual estimated vehicle driving by vehicle age. As can be seen, vehicles in the first three years of their life are driven 17,800-19,900 kilometers per year. Vehicles that are 10-12 years old are driven only 8,200-10,400 kilometers per year. This reduced driving at higher age will reduce the impact of older vehicles on air pollution. Table 3.5 also presents similar data for the United States [U.S. EPA]. As can be seen U.S. drivers drive more than Nairobi drivers, and the U.S. shows a similar reduction in driving as vehicles age. The significant increase in the ratio of driving in the U.S. at higher ages compared to Nairobi driving is likely the result of the data collection method. There is no way to tell on older vehicles if the odometer has turned over. Thus, for older vehicles, the usage will be underestimated. To correct for this problem, the ratio of driving will be kept at 1.46 (the average ratio over the first 10 years of vehicle life) between Nairobi and U.S. driving for vehicle ages above 10 years of age.

Table 3.5a: Estimated Annual Driving by Vehicle Age

Vehicle Age (years)	Projected Nairobi Accumulated Driving (Km)	Annual Nairobi Driving (Km)	Annual U.S. Driving (Km) ⁴	U.S./Nairobi Ratio
1	18,565	18,565	26,917	1.45

22	234,831	5,138
23	239,574	4,743
24	243,934	4,360
25	247,782	3,848

An important adjunct to the accumulated mileage and the typical mileage driven per year is the distribution of driving associated with each age group. Figure 3.4 and Table 3.5 above present averages derived from the whole data set. Figure 3.6 presents the distribution of driving around the average accumulated vehicle usage. The data for Figure 3.6 was developed by dividing the average vehicle usage projected using the second-order equation in Figure 3.4 into the actual usage recorded for each vehicle surveyed for which an odometer reading was available. This curve provides an indication of the fractions of drivers that exceed fall below driving norms.

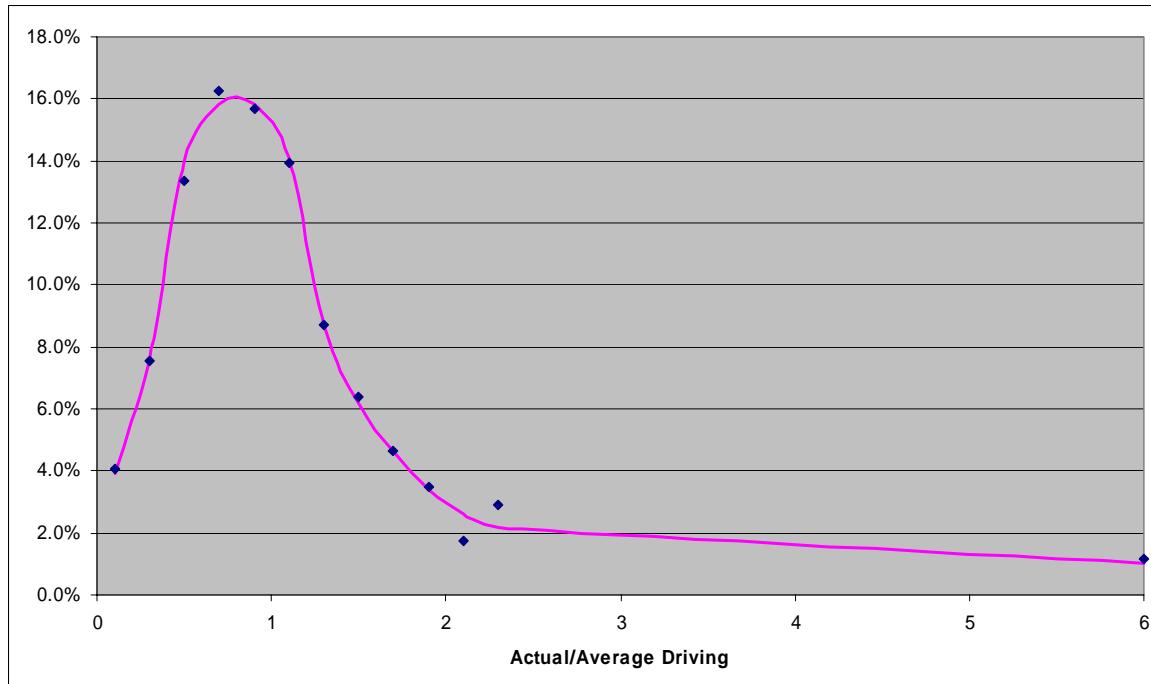

Figure 3.6: Distribution of Driving Around Projected Accumulated Usage

Taxis

Only limited Taxi data was collected. The entire sample consists of 30 vehicles. All taxis surveyed were bought as used vehicles and the drivers reported that virtually taxis are bought today as used vehicles. The typical taxi was 5.4 years old when purchased based on the difference between vehicle model year and vehicle registration year. The average accumulated mileage on the odometers was 122,480 km. The 30 taxi drivers indicated that they drove between 20 and 240 km per day depending upon the taxi driver. The higher daily driving was reported by taxi drivers representing larger taxi companies while the lower daily driving was reported by freelance taxi drivers. The average of the daily driving estimates by the taxi drivers was 99 km per day at 365 days per year, which translates to 36,000 km per year. It is notable that the Santiago taxi analysis indicated that they drove 35,000 km per year, which is very consistent with the Nairobi results. The limited number of taxi odometer readings makes any regression analysis of the data suspect. Since taxis in Nairobi are purchased off of the same market as consumer vehicles, it is assumed for this analysis, that the original odometer reading conformed to the amounts observed with the rest of the vehicles analyzed earlier. This implies a value of 4989 km per year of age before arriving in Kenya. Using this value in a second order regression on the taxi data produces the result:

$$\text{Accumulated Use (km)} = 4,989 * (\text{Yrs Before Kenya}) + 24,880 * (\text{Yrs in Kenya}) - 855.5 * (\text{Yrs in Kenya})^2$$

This result, while indicating greater driving than non-taxi passenger vehicles, is at variance with the annual driving reported by the taxi drivers of 36,000 km per year. We have no explanation for this discrepancy unless the observed odometers have turned over one or more times or if taxi drivers also have a tendency to disconnect their odometers where possible. The estimates reported by the taxi drivers will be used rather than the odometer readings collected in this study.

The average engine size for taxis was 1.5 liters and 93% were gasoline and 7% diesel. All vehicles except one were in the 1.5/1.6 liter engine size. Figure 3.7 shows the model year distribution of the taxi fleet compared to the normal fleet.

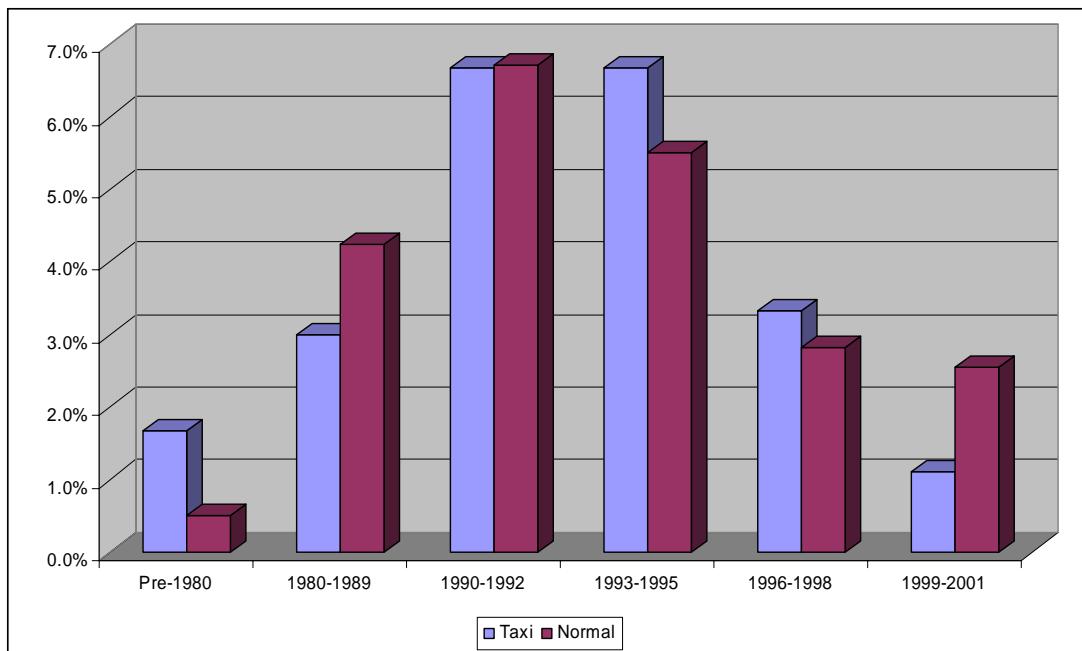

Figure 3.7: Model Year Distribution of Taxis for Nairobi

As can be seen, the model year distribution observed for the taxi fleet is consistent with that observed for the overall fleet with the exception of very new vehicles. It appears that taxi companies tend to stay away from very new vehicles based on this data.

Chapter Four: Vehicle Technology Matrix Based on Video

The International Vehicle Emissions model (IVE model), which this study is designed to support, categorizes on-road vehicles into 871⁵ technology categories. The large number of technologies derives from the fact that the IVE model is intended to accommodate a wide array of urban areas around the world and to project emissions in these areas into the future. Thus, fuels as diverse as gasoline, diesel, ethanol, and natural gas must be accommodated along with a wide variety of control technologies for the passenger fleet, truck fleet, bus fleet, and for motorcycles. Appendix B shows the 871 technologies presently accommodated by the model.

As noted earlier, the videotapes were used to create a general breakdown of the on-road fleet. The stationary vehicle data was used to further break the passenger fleet into more finely divided subsets. The data was parsed on an excel spreadsheet into the categories of interest. Table 4.1 indicates the values used to parse the data.

Table 4.1: Values Used to Parse Data

	Vehicle Size (based on engine size in liters)	Vehicle Usage (based on amount driven or model year in thousands of Km)⁶
Small/Low	0.5-1.5	0-79
Medium/Medium	1.6-2.4	80-159
Large/High	2.5-5	160-1,000

Using Tables 2.2 a, b, c a breakdown of on-road vehicle use was created and is shown in Table 4.2. The values shown in Table 4.2 were created by equally weighting the highway (freeway), arterial, and residential information and averaging it. The overall fleet data are created by equally weighting all of the video produced data and averaging it. A more accurate distribution can be created by determining the relative amount of driving that is occurring on residential streets compared to arterial streets compared to highways and

⁵ As more experience is gained in different locations it has been necessary to increase the technology choices. For example, when the model was first designed, it was assumed that all closed loop engine technologies would also include some form of catalyst and EGR. However, it was discovered in Chile that many closed loop engine technologies did not have EGR. In Kenya it was determined that the leaded fuel in use there will have rendered the catalyst ineffective so that in effect, these vehicles were operating without a catalyst.

⁶ In cases where the odometer reading was visible, the value observed on the odometer was used. If no odometer reading was observable then a vehicle usage was approximated using the second order least squares fit equation shown in Figure 3.5. This projected odometer reading was then used to locate the vehicle in the proper use bin.

weighting the activity data. Similarly an improved overall data set can be developed by determining the relative amount of driving that is occurring in Buruburu like situations compared to Central Nairobi type situations compared to Muthaiga type situations. This information is not available at the present. Thus, equal weighting is being used for the present.

Table 4.2: Breakdown of Vehicular Activity Based on Video Tapes of Nairobi Traffic Compared to Santiago Traffic

		Passenger Vehicles	Taxis ⁷	Medium Sized Trucks	Large Sized Trucks	Small Sized Buses	Medium Sized Buses	Large Sized Buses	Motorcycles
Overall Fleet	Santiago	81.1%	9.2%	4.5%	0.6%	0.9%	0.4%	4%	1.4%
	Nairobi	88.6%	0.36%	5.4%	1.2%	1.2%	1.1%	0.6%	1.5%
Lower Income Area	Santiago	78.9%	11.8%	4.7%	0.7%	0.9%	0.9%	1.5%	0.6%
	Nairobi	86.8%	0.09%	7.9%	1.9%	0.9%	0.5%	0.5%	1.6%
Commercial Area	Santiago	74.7%	8.7%	5.6%	1.2%	0.1%	0.3%	7.8%	1.7%
	Nairobi	90.1%	0.7%	2.4%	0.7%	1.6%	2.1%	0.8%	1.8%
Upper Income Area	Santiago	85.1%	6.4%	1.9%	0.1%	1.8%	0.1%	2.9%	1.7%
	Nairobi	90.0%	0.5%	4.8%	0.5%	1.3%	1.2%	0.6%	1.1%

The parked car passenger vehicle information can be used to parse the passenger vehicle fractions into sub-fractions. This is accomplished by multiplying the parked car fractions for the area of interest by the overall passenger vehicle fractions in Table 4.2. The results can be found in Appendix C.

As discussed in Section 3, this process assumes that the observed vehicle fractions in the case of parked cars correspond to the relative use (activity) of these vehicles. Although one would expect the parked vehicle distributions to conform reasonably well to vehicle activity, this has not been proven to be the case. The Los Angeles study associated with this work adds credibility to this assumption. In the Los Angeles study, the video data was used to collect license plate data. The license plate data allowed the specific determination of vehicle technology for the moving fleet. This was compared with data collected in parking lots and the data was in good agreement.

This technology identification portion of the study did not include data collection concerning diesel trucks and buses. Thus, no data was available to parse diesel vehicles into various age or technology categories. For the present analysis, all diesel trucks and buses are considered to be uncontrolled using pre-chamber injection technology. The vehicles were broken arbitrarily half into the normal category and half into the improved category. The age distributions were estimated based on U.S. data [U.S. EPA]. Table 4.3 indicates the factors used to parse the truck and bus data into age bins. Motorcycles were assumed to be half 2-cycle and half 4-cycle and of less than 79,000 Km (50,000 miles) based on discussions with CONAMA and Nairobi officials. This assumption needs to be tested based on future studies.

⁷It is likely that the Nairobi taxi fleet is significantly undercounted. Taxis are not required to be marked in Nairobi; thus, it is not possible to distinguish many of the taxis from normal passenger vehicles.

Table 4.3: Assumptions Used to Parse Truck and Bus Data into Age Bins

Vehicle Type	Vehicle Size		
	Low Use	Medium Use	High Use
Medium Truck	16.3%	15.5%	68.2%
Large Truck	13.0%	13.0%	74%
Small Bus	13.0%	13.0%	74%
Medium Bus	13.0%	13.0%	74%
Large Bus	13.0%	13.0%	74%

As noted earlier, the results for the overall Nairobi metro area and for the Buruburu, Central Nairobi, and Muthaiga districts are shown in Appendix C.

Appendix B

On-Road Vehicle Technologies Allowed in IVE Model

Vehicle Technologies Used in the IVE Model

Description	Fuel	Weight	Air/Fuel Control	Exhaust Control	Evaporative Control	Age	Index	Fraction of Miles Driven Standard Vehicles	Fraction with AC Standard Vehicles
Automobile/Small Truck	Gasoline	Light	Carburetor	None	PCV	0-50K miles (0-79K km)	0		
Automobile/Small Truck	Gasoline	Light	Carburetor	None	PCV	51K-100K miles (80K-161K km)	1		
Automobile/Small Truck	Gasoline	Light	Carburetor	None	PCV	>100K miles (>162K km)	2		
Automobile/Small Truck	Gasoline	Medium	Carburetor	None	PCV	0-50K miles (0-79K km)	3		
Automobile/Small Truck	Gasoline	Medium	Carburetor	None	PCV	51K-100K miles (80K-161K km)	4		
Automobile/Small Truck	Gasoline	Medium	Carburetor	None	PCV	>100K miles (>162K km)	5		
Automobile/Small Truck	Gasoline	Heavy	Carburetor	None	PCV	0-50K miles (0-79K km)	6		
Automobile/Small Truck	Gasoline	Heavy	Carburetor	None	PCV	51K-100K miles (80K-161K km)	7		
Automobile/Small Truck	Gasoline	Heavy	Carburetor	None	PCV	>100K miles (>162K km)	8		
Automobile/Small Truck	Gasoline	Light	Carburetor	2-Way	PCV	0-50K miles (0-79K km)	9		
Automobile/Small Truck	Gasoline	Light	Carburetor	2-Way	PCV	51K-100K miles (80K-161K km)	10		
Automobile/Small Truck	Gasoline	Light	Carburetor	2-Way	PCV	>100K miles (>162K km)	11		
Automobile/Small Truck	Gasoline	Medium	Carburetor	2-Way	PCV	0-50K miles (0-79K km)	12		
Automobile/Small Truck	Gasoline	Medium	Carburetor	2-Way	PCV	51K-100K miles (80K-161K km)	13		
Automobile/Small Truck	Gasoline	Medium	Carburetor	2-Way	PCV	>100K miles (>162K km)	14		
Automobile/Small Truck	Gasoline	Heavy	Carburetor	2-Way	PCV	0-50K miles (0-79K km)	15		
Automobile/Small Truck	Gasoline	Heavy	Carburetor	2-Way	PCV	51K-100K miles (80K-161K km)	16		
Automobile/Small Truck	Gasoline	Heavy	Carburetor	2-Way	PCV	>100K miles (>162K km)	17		
Automobile/Small Truck	Gasoline	Light	Carburetor	2-Way/EGR	PCV	0-50K miles (0-79K km)	18		
Automobile/Small Truck	Gasoline	Light	Carburetor	2-Way/EGR	PCV	51K-100K miles (80K-161K km)	19		
Automobile/Small Truck	Gasoline	Light	Carburetor	2-Way/EGR	PCV	>100K miles (>162K km)	20		
Automobile/Small Truck	Gasoline	Medium	Carburetor	2-Way/EGR	PCV	0-50K miles (0-79K km)	21		
Automobile/Small Truck	Gasoline	Medium	Carburetor	2-Way/EGR	PCV	51K-100K miles (80K-161K km)	22		
Automobile/Small Truck	Gasoline	Medium	Carburetor	2-Way/EGR	PCV	>100K miles (>162K km)	23		
Automobile/Small Truck	Gasoline	Heavy	Carburetor	2-Way/EGR	PCV	0-50K miles (0-79K km)	24		
Automobile/Small Truck	Gasoline	Heavy	Carburetor	2-Way/EGR	PCV	51K-100K miles (80K-161K km)	25		
Automobile/Small Truck	Gasoline	Heavy	Carburetor	2-Way/EGR	PCV	>100K miles (>162K km)	26		
Automobile/Small Truck	Gasoline	Light	Carburetor	3-Way	PCV	0-50K miles (0-79K km)	27		
Automobile/Small Truck	Gasoline	Light	Carburetor	3-Way	PCV	51K-100K miles (80K-161K km)	28		
Automobile/Small Truck	Gasoline	Light	Carburetor	3-Way	PCV	>100K miles (>162K km)	29		
Automobile/Small Truck	Gasoline	Medium	Carburetor	3-Way	PCV	0-50K miles (0-79K km)	30		
Automobile/Small Truck	Gasoline	Medium	Carburetor	3-Way	PCV	51K-100K miles (80K-161K km)	31		
Automobile/Small Truck	Gasoline	Medium	Carburetor	3-Way	PCV	>100K miles (>162K km)	32		
Automobile/Small Truck	Gasoline	Heavy	Carburetor	3-Way	PCV	0-50K miles (0-79K km)	33		
Automobile/Small Truck	Gasoline	Heavy	Carburetor	3-Way	PCV	51K-100K miles (80K-161K km)	34		
Automobile/Small Truck	Gasoline	Heavy	Carburetor	3-Way	PCV	>100K miles (>162K km)	35
